- Chen and Chen, DeepONet

Motivation: Solving PDEs

Seek to solve PDE problems of the form

$$\mathbf{u}_t = F(\mathbf{x}, u, \nabla u, \nabla^2 u) \quad \text{with BC}$$

$$u(\mathbf{x}, 0) = u_0(\mathbf{x}) \in H^1.$$

eg.

$$-\Delta u = f(x), \quad iu_t + \Delta u + u|u|^2 = 0, \quad u_t = \Delta u + f(x, u).$$

In the previous lecture we saw how the solution $u_T(x) \equiv u(x, T)$ could be described using an operator over an infinite dimensional function space

Now use machine learning to approximate this operator over a subset of H^1

Operator based methods such as FNO

Idea: Evolutionary PDE defined for $x \in \Omega$

$$u_t = F(x, t, u, u_x, u_{xx}), \quad u(0, x) \equiv u_0(x) \in H^1(\Omega).$$

If $u_T(x) \equiv u(T, x)$ this *can* induce a **map** $N : H^1(\Omega) \rightarrow H^1(\Omega)$

$$N : u_0 \equiv u_T$$

- If F is **linear** then so is N . Otherwise **nonlinear**
- If F is **Lipschitz** then N is **continuous**. Otherwise properties of N are **unclear** and it may not even exist!
- If u satisfies a **conservation law** then so should N .

Neural operator methods try to learn the map N . Most literature is for the linear case. At best for the Lipschitz case

Basic construction

Assume that

$$u_T = N(u_0), \quad N : H^1 \rightarrow H^1 \quad (\text{or similar}), \quad N \text{ continuous}$$

- Use a high accurate 'traditional' or PINN based numerical method to construct a **training set** comprising a large number of **solution pairs**

$$(u_0^i, u_T^i), \quad i = 1 \dots M \quad M \gg 1$$

- Train a NN to find a **Neural Operator** $\Psi : H^1 \rightarrow H^1$ so that

$$L = \sum_i \|\Psi(u_0^i) - u_T^i\|^2$$

(or similar) is minimised over the training set

- Test over a suitable test set of solution pairs
- If valid, use Ψ as an **emulator** for the PDE, for example in control applications or uncertainty quantification or weather forecasting

Notes

- Many different architectures for NN. Many make use of latent **finite dimensional** structures. Examples include **DeepONet** and **FNO**.
- This is **supervised learning of the operator** as we are generating the pairs in advance. **It differs significantly from the semi-supervised training of a PINN.**
- Quality of the NN depends significantly on the quality of the training set.
- Various theorems exist on the convergence/accuracy of the Neural operator. They rely on properties of N which depend in a very subtle way on the properties of the underlying PDE. See [Kovachi et. al.]

Before we start

Some key issues with the construction of the Neural Operator

- How to construct an operator over on infinite dimensional space
- Architecture of the NN (FNO, DeepONet, CNO) etc.
- Selection of the training set (convex hulls etc.)
- Convergence as $W, L, M \rightarrow \infty$
- Building in the physics (conservation laws etc.)

Example

Simplest example is the **linear heat equation**

$$u_t = u_{xx}, \quad x \in \Omega.$$

Then have if $\Omega = \mathbb{R}$ we have the **convolution**

$$N : u_0 \rightarrow u_1 \equiv G * u_0 \equiv \frac{1}{\sqrt{2\pi t}} \int_{-\infty}^{\infty} e^{-(x-y)^2/t} u_0(y) dy.$$

Also if u satisfies **periodic boundary conditions** $x \in [0, 2\pi]$

$$N : u_0(x) \equiv \sum_n a_n e^{inx} \rightarrow u_1(x) \equiv \sum_n e^{-n^2} a_n e^{inx}.$$

So the linear map N is defined in terms of **convolutional integral operators** and **simple spectral operations**.

The FNO: In general

The **FNO architecture** is based on the process of solving the linear heat equation:

$$\Psi(a, \theta)_{FNO} \equiv Q \circ \mathcal{L}_L \circ \dots \circ \mathcal{L}_2 \circ \mathcal{L}_1 \circ P(a).$$

$$\mathcal{L}_n(v)(x, \theta) = \sigma(W_n v(x) + b_n + K(v))$$

Here W is a **pointwise linear local map**. $K(v)$ is a **global convolutional integral operator**, kernel $G_n(\theta)$. Evaluate Kv using an **FFT** via

$$FFT(Kv) = FFT(G_n) FFT(v).$$

FFT restricted to M modes. Nonlinearity and **higher order modes** introduced via the **activation function** σ .

Figure from FNO paper

The screenshot shows a web browser displaying the GitHub repository for **NeuralOperator**. The repository is titled "NeuralOperator: Learning in Infinite Dimensions". The main content area includes a description of the library, its installation instructions, and a quickstart section. The right sidebar shows the repository's statistics, including 31 contributors, 211 deployments, and 100.0% Python code coverage.

NeuralOperator: Learning in Infinite Dimensions

`neuraloperator` is a comprehensive library for learning neural operators in PyTorch. It is the official implementation for Fourier Neural Operators and Tensorized Neural Operators.

Unlike regular neural networks, neural operators enable learning mapping between function spaces, and this library provides all of the tools to do so on your own data.

Neural operators are also resolution invariant, so your trained operator can be applied on data of any resolution.

Installation

Just clone the repository and install locally (in editable mode so changes in the code are immediately reflected without having to reinstall):

```
git clone https://github.com/NeuralOperator/neuraloperator
cd neuraloperator
pip install -e .
pip install -r requirements.txt
```

You can also just pip install the most recent stable release of the library on [PyPI](#):

```
pip install neuraloperator
```

Quickstart

After you've installed the library, you can start training operators seamlessly:

Examples

NeuralOperator Developer's Guide

User Guide

NeuralOperator provides all the tools you need to easily use, build and train neural operators for your own applications and learn mapping between function spaces, in PyTorch.

Intro to operator learning

To get a better feel for the theory behind our neural operator models, see [Neural Operators: an introduction](#). Once you're comfortable with the concept of operator learning, check out specific details of our Fourier Neural Operator (FNO) in [Fourier Neural Operators](#). Finally, to learn more about the model training utilities we provide, check out [Training neural operator models](#).

NeuralOperator library structure

Here are the main components of the library:

Module	Description
<code>neuralop</code>	Main library
<code>neuralop.models</code>	Full ready-to-use neural operators
<code>neuralop.layers</code>	Individual layers to build neural operators
<code>neuralop.data</code>	Convenience PyTorch data loaders for PDE datasets

- Interactive examples with

FNO in detail 1

- **Input** $a_j(x) \in \mathcal{A}$ **output** $u_j(x) = N(a_j) \in \mathcal{U}$ are **functions** on $x \in D \subset \mathbb{R}^d$
- Assume have access to pointwise observations of a only at points in $x_i \in D_j \subset D$. **Output u does not depend on D_j : super-resolution**
- **Lift** a to a higher dimensional representation $v_0(x) = P(a(x))$ by a shallow NN.
- Calculate a series of updates $v_n \rightarrow v_{n+1}$ via the local W_n and global (integral) K_n operators:

$$v_{n+1}(x) = \sigma(W_n v_n(x) + (K_n(\theta) v_n))(x).$$

- For example $\sigma = \text{ReLU}$: This introduces **nonlinearity** into the map.
- **Project** $v_L \rightarrow u(x) = Q(v_L)$
- **Learn** P, Q, W_n, K_n from the data pairs

FNO in detail 2

If $u(x), x \in R^d$ have Fourier Transform (FT)

$$F(u)(\omega) = \int e^{-i\omega \cdot x} u(x) dx.$$

If $u_k = u(x_k)$, with $x_k \in R, k = 0 \dots N-1$ have DFT approximation

$$F_j = \sum_{k=0}^{N-1} e^{-2\pi i j k / N} u_k, \quad u_k = \frac{1}{N} \sum_{j=0}^{N-1} e^{2\pi i j k / N} F_j$$

with a natural extension to d -dimensions.

This can be evaluated very rapidly using the FFT `np.fft.fft` in Python

Implement the FNO using the FFT to calculate all Fourier Transforms.
Efficient, but requires a **uniform discretisation of $u(x)$** .

If K is a convolutional kernel with Fourier Transform G then

$$FT(K * u) = FT(K)FFT(u) = GFT(u)$$

Hence if we have a FFT approximation G_j to G

Truncate the number of modes through the DFT.

The nonlinearity of the activation function σ

generates higher order modes automatically, albeit in a somewhat uncontrolled manner!

Training

- Assume input $a \in \mathcal{A}$
- In the original FNO paper take a_j as an i.i.d sequence from \mathcal{A} .
- Construct pairs $(a_j, N(a_j))$ using an accurate solver eg. pseudo-spectral method
- In FNO paper take $N = 1000$ training and 200 training instances. Adam optimiser to find parameters θ via:

$$\min_{\theta} E_{a \sim \mu} [\|\psi(a, \theta) - N(a)\|]$$

- Can significantly improve training by a more careful selection of input and output pairs [Liu, B, et. al.]

More examples

Burgers Equation

$$u_t + uu_x = \nu u_{xx}, \quad \nu \ll 1, \quad \text{periodic BC}$$

$$N : u_0(x) \rightarrow u_1(x).$$

Darcy Flow

$$-\nabla \cdot (a(x) \nabla u) = f(x), \quad x \in [0, 1] \times [0, 1] \quad u = 0, \quad x \in \partial[0, 1] \times [0, 1].$$

$$N : a \rightarrow u.$$

Left: benchmarks on Burgers equation; Mid: benchmarks on Darcy Flow for different resolutions; Right: the learning curves on Navier-Stokes $\nu = 1e-3$ with different benchmarks. Train and test on the same resolution. For acronyms, see Section 5; details in Tables 1, 3, 4.

Figure 3: Benchmark on Burger's equation, Darcy Flow, and Navier-Stokes

More Examples:

2D Allen-Cahn equation modeling phase separation:

$$\begin{aligned} u_t &= u - u^3 + \epsilon^2 \Delta u, & \mathbf{x} \in [0, 1]^2, t \in (0, T) \\ u(0, \mathbf{x}) &= u_0(\mathbf{x}), & \mathbf{x} \in [0, 1]^2 \end{aligned} \tag{1}$$

Navier-Stokes eqns (vorticity formulation)

$$\begin{aligned} \omega_t &= -u \cdot \omega_x - v \cdot \omega_y + \nu \Delta \omega + f, & \mathbf{x} \in [0, 1]^2, t \in (0, T) \\ \omega &= v_x - u_y, & w(0, \mathbf{x}) = w_0(\mathbf{x}), & \mathbf{x} \in [0, 1]^2, \end{aligned} \tag{2}$$

Results on Allen-Cahn

Predictions of FNO trained on different datasets for the Allen-Cahn equation ($\epsilon = 0.05$). (a) inputs with noise (b) 1000 data pairs (c) 10000 data pairs (d) 1000 data pairs + 1000 generated data pairs (e) 5000 data pairs + 5000 generated data pairs (f) ground truth [with Chaoyu Liu]

Navier-Stokes equation ($\nu = 0.001, \Delta t = 0.5$):

Figure: The first two columns are generated inputs and outputs from the inverse evolution, respectively. The last column shows the true solutions of the generated input.

Results on Navier-Stokes

Test error of neural operators on PDE datasets with 1000 and 10000 training samples.

Linear Conservation Equations

- **Conservative Allen-Cahn Equation:**

$$u_t = \nabla \cdot (\epsilon \nabla u) + u - u^3 - \frac{1}{|\Omega|} \int_{\Omega} u - u^3 d\mathbf{x}, \quad \mathbf{x} \in \Omega, \quad t > 0,$$

$\int u \, d\mathbf{x}$ is conserved

- **Shallow Water Equations:**

$$\begin{cases} h_t + \nabla \cdot (h\mathbf{u}) = 0, \\ (h\mathbf{u})_t + \nabla \cdot (h\mathbf{u} \otimes \mathbf{u} + \frac{1}{2}gh^2\mathbf{I}) = 0, \end{cases} \quad \mathbf{x} \in \Omega, \quad t > 0,$$

Norm Conservation Equations

- **Transport Equation:**

$$u_t + \nabla \cdot (u\mathbf{v}) = 0, \quad x \in \Omega, \quad t > 0.$$

The L^2 norm of u is conserved over time.

- **Schrödinger Equations:**

$$\text{Linear: } i\psi_t + \frac{1}{2}\Delta\psi + V(x)\psi = 0, \quad x \in \Omega, \quad t > 0,$$

$$\text{Nonlinear: } i\psi_t + \frac{1}{2}\Delta\psi + \lambda||\psi||^2\psi = 0, \quad x \in \Omega, \quad t > 0,$$

Conservation of the L^2 -norm $\int_{\Omega} |\psi(\mathbf{x}, t)|^2 d\mathbf{x}$. Fundamental in quantum mechanics. Also quartic-power conservation for NLS

Conservation Laws	Equation	FNO	Loss	Liu and B

Table: **Conservation error** for the original FNO, the FNO with conservation included in the loss function, and the adaptive correction method.

Areas for improvement and research on FNO

- Observe poor conservation laws at the moment
- Generating a **good training set** is crucial and can be **slow**. How to make it good and fast?
- FNO struggles away from the training set. This is OK for MCMC emulators for UQ.
- BUT Need to broaden its scope and extend the theorems on its convergence
- NONE of this theory applies, for example, to the **nonlinear** heat equation

$$u_t = u_{xx} + u^2.$$

Idea [Chen and Chen] : Approximate map $N : \mathcal{U} \rightarrow \mathcal{V}$

$$N \approx \psi = G_{\mathcal{V}} \circ NN \circ F_{\mathcal{U}}$$

By training the NN with **encoder** $F_{\mathcal{U}}$ and **decoder** $G_{\mathcal{V}}$.

- Make use of principal component analysis (PCA)
- Input space \mathcal{U} with input (functions) from a probability measure μ .
- Construct principal components from the **Covariance** of μ .

See [Broomhead and King 1983] for the first use of this idea to reconstruct a dynamical system from data, coupled to a radial basis function architecture

- PCA basis functions ϕ_i
- **Encoder** $F_{\mathcal{U}}$ a linear map $L : \mathcal{U} \rightarrow R^{d_{\mathcal{U}}}$ (typically) projects onto first $d_{\mathcal{U}}$ basis functions

$$Lu_i = \langle u, \phi_i \rangle.$$

-

$$\mathbf{a} = Lu$$

is used as the input to a **finite dimensional feed forward NN** output **b**

- **decoder** $G_{\mathcal{V}}$ given by

$$G_{\mathcal{V}} = \sum_j b_j \phi_j$$

- Train NN on a set of input/output pairs

Convergence [Kovachi et. al.]

- FNO and DeepONet can approximate a wide variety of operators
- Assume that input space \mathcal{U} is a separable Banach space and the map N is compact
- Prove convergence on any finite dimensional set using the universal approximation theorem
- Take an appropriate limit (approximation theory of Banach spaces which applies to the sets over which PDEs are typically formulated)

Summary

- PINNS and NOs both show promise as a quick way of solving PDEs but have only really been tested on quite simple problems so far
- PINS not (yet) competitive with FE in like-for-like comparisons
- PINNs need careful meta-parameter tuning to work well
- NOs proving more promising. Now used for weather forecasting!
- Long way to go before we understand PINNS or NOs completely and have a satisfactory convergence theory for them in the general case.
- Lots of great stuff to do!
